1. *Introduction*

2. *Methodology*

The study was conducted in a laboratory setting with 20 participants. The participants were randomly assigned to two groups: the control group and the experimental group. The control group received a standard treatment, while the experimental group received a modified treatment. The primary outcome variable was the change in blood pressure over a 12-week period. Secondary outcomes included changes in heart rate, cholesterol levels, and quality of life. Data were collected at baseline, 4 weeks, 8 weeks, and 12 weeks. Statistical analysis was performed using SPSS software, and a p-value of less than 0.05 was considered statistically significant. The results showed that the experimental group had a significantly greater reduction in blood pressure compared to the control group. There were no significant differences in heart rate, cholesterol levels, or quality of life between the two groups. The findings suggest that the modified treatment may be more effective than the standard treatment for reducing blood pressure.
