

Figure 33-23. Secondary root growth in a dicot stem. The primary root is shown on the left, and the secondary root is shown on the right. The transition zone is shaded in blue.

The secondary root grows from the pericycle, which is a ring of cells located just inside the endodermis. The secondary root grows outwards, eventually breaking through the cortex and epidermis. The transition zone is the area where the secondary root is forming, and it is shaded in blue in the diagram. The primary root is shown on the left, and the secondary root is shown on the right.
